Answer: IaC treats infrastructure as immutable, meaning that instead of modifying existing infrastructure components, new instances are created to replace old ones. This approach ensures consistency, reduces configuration drift, and simplifies rollback.

9. Question: Explain the "Plan, Apply, and Destroy" workflow in Terraform.

Answer: In Terraform, you first create an execution plan to preview changes without actually making them (`terraform plan`), then apply the changes to the infrastructure (`terraform apply`), and finally, you can destroy the created resources (`terraform destroy`) when they are no longer needed.

10. Question: How does IaC enhance collaboration between development and operations teams?

Answer: IaC provides a common language for both teams, making it easier to define infrastructure requirements and changes. This reduces misunderstandings and misconfigurations between teams.

11. Question: Describe the process of using IaC for creating a virtual machine instance.

Answer: To create a virtual machine instance using IaC, you would define its properties (such as size, image, network settings) in a template file (e.g., Terraform's `.tf` file). Then, you would use the IaC tool to apply the

configuration, which would provision the virtual machine according to the template.

Answer: Serverless orchestration involves coordinating multiple serverless functions to achieve a specific workflow or task. Cloud services like AWS Step Functions or Azure Logic Apps provide tools for designing and managing these workflows in a serverless environment.

21. Question: How can DevOps practices be integrated into the deployment of machine learning models on cloud platforms?

Answer: DevOps practices can be applied to machine learning model deployment by automating model training, testing, and deployment processes. Using tools like Azure Machine Learning or AWS SageMaker, DevOps teams can achieve continuous integration and delivery for machine learning pipelines.

22. Question: Explain the concept of "Infrastructure as Code" (IaC) drift and how it can be managed in cloud environments.

Answer: IaC drift refers to the inconsistencies between the defined infrastructure state in code and the actual deployed state. In cloud environments, drift can be minimized by regularly comparing the defined state with the actual state and using automation to correct discrepancies.

23. Question: How do cloud services contribute to Disaster Recovery (DR) strategies in DevOps?

Answer: Cloud services provide options for replicating data and applications across regions or cloud providers, enhancing Disaster Recovery capabilities. DevOps teams can automate DR processes to ensure rapid recovery in case of failures.

24. Question: Describe the role of Cloud-native Continuous Integration (CI) tools in DevOps workflows.

Answer: Cloud-native CI tools, like AWS CodePipeline or Azure DevOps, enable DevOps teams to automate the build, test, and deployment processes in cloud environments. These tools integrate with various cloud services and streamline the development lifecycle.

25. Question: How can DevOps teams ensure compliance and auditing in a cloud-based environment?

Answer: DevOps teams can enforce compliance by defining security policies as code, using cloud-native services for identity and access management, and regularly conducting audits. Tools like AWS Config and Azure Policy help enforce and monitor compliance rules.
